

FOLDABLE BOX**OBJECT OF THE INVENTION**

The present invention refers to a foldable box, of the type comprising: rigid sides, at least one flexible
5 sheet connecting the rigid sides forming hinging means which permit the arrangement of said sides
forming a hollow, polygonal prismatic configuration, as well as the overlapping thereof, the box
adopting a flattened configuration, and covers intended for closing the box bases when the sides
define a prismatic configuration; each one of the covers being composed of an outer part with slightly
larger dimensions than the inner cavity of the prismatic configuration and of an inner part intended to
10 be introduced inside of said prismatic configuration when in the closed position.

BACKGROUND OF THE INVENTION

Currently, different foldable boxes provided with rigid sides exist on the market, connected together
by means of one or more flexible sheets permitting the relative rotation of said rigid sides in order to
15 form a hollow prismatic configuration or overlapping thereof, the box adopting a flattened
configuration which permits reducing the volume occupied by the box when it is not in use.

Spanish Utility Model application number 248,234 discloses an improved container of the type of
those constituted by semirigid material sandwich-type panels, connected together by means of flexible
sheets fixed to the opposite ends of the panels and acting like a hinge.

20 In said Utility Model 248,234, the ends of the flexible sheets are housed and fixed between two of the
layers of the sandwich-type panels constituting the sides of the box, so that said sheets remain in a
visible position once the box is formed.

The length of the flexible sheets arranged between the successive panels implies an important
drawback because once the container is assembled, it permits the sides thereof to have freedom,
25 making the definition of a regular prismatic body and of a stable configuration significantly difficult.

Said Utility Model 248,234 also foresees that the container be provided with independent covers
which subsequently will be fixed to the container body for the purpose of carrying out the closure of
the bases thereof.

The use of dismountable container covers implies an additional drawback because said covers can be
30 lost during storage or transport of the container, so that when the assembly of said container is carried
out, the necessary elements to carry out its closure will not be available.

Spanish Utility Model application number 9,700,240 discloses a foldable box, which, like in the prior Utility Model, is composed of wooden sides connected together by means of a paper sheet reinforced by means of mesh, permitting said sheet the rotation or relative flattening of the sides, so that the box can adopt a prismatic configuration when in use, or a flattened configuration in which the space necessary for its transport is reduced.

Identically as in the aforementioned model, the foldable box of the utility model 9,700,240 contemplates fixing the wooden sides to the paper sheet reinforced with a mesh, leaving between the two wooden sides spaces acting like a hinge.

Identically as in the prior case, the portions of the reinforced paper sheet which remain between the rigid wooden sides considerably reduce the stability of the box once it is assembled, because it permits certain freedom to said rigid sides.

Likewise, the use of a paper sheet reinforced with mesh for the connection of the rigid sides implies an unnecessary increase in manufacturing costs of the box.

In said Utility Model 9,700,240, the use of covers is also contemplated, covers independent from the box body itself, which implies, as in the prior case, a risk of the loss thereof during transport or storage of the box in a disassembled state.

On the other hand, said registered background does not contemplate the use of any specific means which permit carrying out the retention of the cover in the closed position and its subsequent opening for the purpose of making it possible to reuse the box as many times as required.

DESCRIPTION OF THE INVENTION

The foldable box object of the invention, being of the aforementioned type, in other words, of those comprising rigid sides connected together by means of flexible sheets and closing covers, have constructive particularities focused on reducing manufacturing costs, especially in reference to the flexible sheet, to eliminate unnecessary allowances between the rigid panels forming the sides, to keep the covers permanently connected to the rest of the box, preventing the loss thereof, and providing it with closure means which permit repeatedly carrying out the retention of the covers in the closed position or its release, so that said box can be totally reusable.

According to the invention, the flexible sheet is entirely formed by a single layer of cardboard, in other words, without reinforcement meshes, which permits significantly reducing the cost of said sheet, there being defined in said flexible sheet by means of fold lines: contiguous portions whose total surface coincides with that of the rigid sides, a lateral flap extending from one of the contiguous end portions and which is fixed on the other contiguous end portion, said sheet defining a polygonal

tubular configuration, and two flaps: an upper one and a lower one, which extend from two of the contiguous portions forming means for the permanent fixing of the covers to the rest of the box.

According to the aforementioned, the surface of the contiguous portions defined on the flexible sheet coincides with that of the rigid sides of the box, so that the opposite sides of said sides make contact together when they are in a coplanar arrangement, thereby ensuring that, in the box assembly condition, they will not remain spaced by an intermediate flexible sheet portion, which provides the box a better stability in the assembly position.

On the other hand, this feature significantly facilitates the tasks of fixing the rigid sides to the flexible sheet, since said fixing is carried out flat and the facing sides of the successive rigid sides connecting together, preventing these from being misaligned, which in reality happens to those boxes which leave a portion of the flexible sheet free between the successive rigid sides.

The definition of a lateral flap on the flexible sheet for fixing the flexible sheet on itself, such that said sheet defines a tubular configuration, significantly simplifies the box manufacturing tasks.

Furthermore, the definition of the two flaps on the flexible sheet, an upper one and a lower one, for holding the covers ensures that these remain permanently connected to the rest of the box, eliminating the risk of loss during the transport and the subsequent drawbacks that this implies.

According to the invention, the sides of the box opposite to the carriers of the flaps for fixing the covers, have holes for the assembly of pins whose ends are housed in holes made for that purpose in the inner parts of the corresponding covers, said pins carrying out the retention of the respective covers in the box closed position.

The existence of said holes and pins permits the box to be opened and closed as many times as necessary without suffering any kind of damage, which provides it with a reusable character.

According to the invention, the outer end of the pin corresponding to the upper cover of the box is provided with a ring simultaneously forming a pull intended to facilitate the holding and removal of said pin for opening the box, and an element for fixing a label or any other decorative element.

Likewise, it was foreseen that the upper and lower flaps of the flexible sheet have a width which is significantly equal to that of the outer parts of the corresponding covers and a length which is smaller than that of the inner parts.

Said upper and lower flaps are arranged between the inner and outer parts of the corresponding cover and fixed to them. In turn, the inner and outer parts of each one of the covers are fixed directly together by those overlapped surface portions and which are not occupied by the flaps of the flexible sheets arranged between them; in this manner, it is ensured that the inner and outer parts of the covers remain solidly fixed together and also to the corresponding flap of the flexible

sheet.

DESCRIPTION OF THE FIGURES

In order complement the description being made and for the purpose of helping to better
5 understand the features of the invention, a set of drawings is attached to the present specification
which, with an illustrative and non-limiting character, show the following

- Figures 1 and 2 show respective perspective views in front perspective
and in rear perspective of the foldable box object of the invention, with
the covers opened and the retention pins of the covers removed.

10 - Figure 3 shows a perspective view of the box in an intermediate
manufacturing stage in which the flat development of the flexible sheet
can be seen, the rigid sides and the outer parts of the cover being fixed
on one of the sides thereof, whereas the inner parts of the cover,
intended to be fixed on the opposite side of the flaps, are shown
15 disassembled.

- Figure 4 shows a profile view of the box once assembled and folded.

PREFERRED EMBODIMENT OF THE INVENTION

As can be seen in the attached drawings, the box object of the invention is composed of a flexible
20 cardboard sheet (1), rigid sides (2), preferably of wood, covers (3) for closing the box once
assembled and pins (4) for the retention of the covers (3) in the closed position.

On the flexible sheet (1), the following are defined by means of fold lines: contiguous portions
(11) whose surface coincides with that of the rigid sides (2) and intended to be fixed on the inner
sides of said rigid sides (2), a side flap (12) starting from one of the contiguous end portions (11)
25 and intended to be fixed on the contiguous portion (11) of the opposite end, so that said flexible
sheet adapts a tubular configuration, and two flaps (13), extending from the upper and lower parts
of two of the contiguous portions (11), forming the holding means of the covers (3).

Each one of the covers (3) is composed of an outer part (31) and an inner part (32) fixed on the
opposite sides of the flaps (13), so that said covers (3) are arranged in the upper and lower ends of
30 the box.

As can be seen in figure 3, the flaps (13) have a width which is significantly equal to that of the outer parts (31) of the covers and a length smaller than that of the inner parts (32), so that a portion of said inner parts (32) is directly fixed on the outer parts (31) of the corresponding cover.

5 As can be seen in figures 1, 2 and 3 the sides of the box opposite to the carriers of the flaps (13) are provided with holes (21) for the assembly of pins (4) intended to be introduced in holes (33) defined on the inner parts (32) of the covers (3), for the purpose of retaining said covers (3) in the closed position of the box.

10 Likewise, one of the pins (4), specifically the one corresponding to the upper cover of the box, has a ring (41) on its end intended to facilitate the holding and pulling of the pin for releasing it from the box prior to opening said upper cover (3).

Likewise, this ring (41) permits fixing thereon a label or any other decorative element. Having sufficiently described the nature of the invention, as well as a preferred embodiment example, it is stated for opportune effects that the materials, shape, size and arrangement of the described elements can be modified, as long as this implies no alteration of the essential features of the
15 invention claimed below.
